ABSTRACT

This paper examines the transformation of the global nuclear order from Cold War bipolarity to a complex multipolar configuration that renders existing deterrence frameworks inadequate. Through analysis of nuclear force modernization programs, arms control treaty erosion, and emerging technologies, the study argues that the international system has entered a 'Second Nuclear Age' characterized by three defining features: the expansion of nuclear-armed states and the diversification of nuclear arsenals; the near-total collapse of the arms control architecture that managed nuclear competition for six decades; and the introduction of destabilizing technologies—including hypersonic delivery systems, AI-integrated command and control, and tactical nuclear weapons—that compress decision timelines and blur the conventional-nuclear threshold. The paper develops a 'Nuclear Geometry Model' mapping the multiple deterrence relationships that now constitute the global nuclear order, demonstrating that bilateral deterrence concepts are insufficient for a world in which nine nuclear-armed states must simultaneously deter multiple adversaries while reassuring multiple allies. The findings reveal that the risk of nuclear use is higher in 2026 than at any point since the Cuban Missile Crisis, driven not by a single acute crisis but by the structural instability of the multipolar nuclear order.

Keywords: Nuclear Deterrence, Arms Control, Nuclear Proliferation, Hypersonic Weapons, AI Military, Strategic Stability, Second Nuclear Age, Multipolarity

1. Introduction

The nuclear order that maintained precarious stability for six decades is unraveling. The bilateral US-Russian arms control framework that constrained the world's two largest arsenals has effectively collapsed: the INF Treaty was terminated in 2019, the Open Skies Treaty in 2020, and New START—the last remaining bilateral nuclear arms control agreement—was suspended by Russia in February 2023, with its scheduled expiration on February 5, 2026. The nuclear Non-Proliferation Treaty review process has stalled. The Iran nuclear agreement (JCPOA) exists in name only. North Korea continues to expand its arsenal.

Simultaneously, the nuclear landscape is being transformed by the modernization and expansion of arsenals across multiple states. China's nuclear buildup—from approximately 350 warheads in 2020 to an estimated 600 by late 2024 according to the US Department of Defense, with projections of up to 1,000 by 2030—represents the most significant shift in the nuclear balance since the Soviet Union's achievement of rough parity with the United States in the 1970s. India and Pakistan continue to expand their arsenals while developing new delivery systems. The United Kingdom has announced an increase in its warhead stockpile. North Korea has developed the capability to strike the continental United States.

This paper argues that these developments collectively constitute a transition to a 'Second Nuclear Age'—a fundamentally different strategic environment from the Cold War bipolar order that generated the deterrence theories, arms control frameworks, and strategic doctrines currently in use. The paper makes three original contributions: a theoretical framework for understanding multipolar nuclear deterrence; empirical documentation of the arms control collapse and its consequences; and a 'Nuclear Geometry Model' that maps the complex deterrence relationships of the multipolar nuclear order.

2. The Collapse of Arms Control

The arms control architecture that managed nuclear competition from the 1960s through the 2010s has experienced a collapse without precedent since the nuclear age began. Figure 2 presents an assessment of the current status of major arms control agreements, revealing that no significant bilateral or multilateral nuclear arms control agreement is currently functioning as intended.

2.1 The End of Bilateral Arms Control

The expiration of New START in February 2026 without replacement marked the first time since 1972 that no legally binding agreement constrains the US and Russian nuclear arsenals. The treaty's verification provisions—which provided each side with detailed data on the other's strategic forces and permitted on-site inspections—have ceased, eliminating the transparency mechanisms that underpinned strategic stability. The resulting opacity increases uncertainty about each side's capabilities and intentions, fueling worst-case planning assumptions that drive further arsenal expansion.

2.2 The China Factor

China's emergence as a major nuclear power fundamentally complicates the arms control landscape. Beijing has historically rejected participation in bilateral US-Russian arms control, arguing that its much smaller arsenal should not be constrained by frameworks designed for superpowers. As China's arsenal approaches parity with deployed US and Russian forces, this

position becomes increasingly untenable. However, no framework exists for trilateral nuclear arms control, and the political conditions for negotiating one are absent.

3. Destabilizing Technologies

3.1 Hypersonic Delivery Systems

The proliferation of hypersonic weapons—maneuverable vehicles traveling at speeds exceeding Mach 5—introduces new instabilities into the nuclear balance. Hypersonic glide vehicles and cruise missiles combine high speed with unpredictable trajectories, compressing the warning time available to defenders and complicating the distinction between conventional and nuclear attack. Russia's Avangard hypersonic glide vehicle, China's DF-ZF, and the US's developmental programs are creating a new dimension of strategic competition that existing deterrence frameworks do not adequately address.

3.2 AI in Nuclear Command and Control

The integration of artificial intelligence into nuclear command, control, and communications (NC3) systems poses perhaps the most profound challenge to strategic stability. AI systems offer the potential for faster threat assessment and response, but they also introduce risks including algorithmic bias, adversarial manipulation, and the compression of human decision-making time in nuclear crisis scenarios. The prospect of AI systems providing launch recommendations—or even possessing delegated launch authority—raises existential questions about human control over nuclear weapons that the strategic community has barely begun to address.

3.3 Tactical Nuclear Weapons and the Threshold Problem

Russia's extensive non-strategic nuclear arsenal—estimated at approximately 1,558 warheads according to FAS not covered by any arms control agreement—and its declared doctrine of potential nuclear use in response to existential conventional threats has revived concerns about the nuclear threshold. The deployment of tactical nuclear weapons in forward positions, combined with doctrinal concepts that envision their use for 'escalate to de-escalate' purposes, blurs the line between conventional and nuclear war in ways that increase the risk of nuclear employment during a conventional conflict.

4. The Nuclear Geometry Model

This paper proposes the Nuclear Geometry Model as a framework for understanding the multipolar nuclear order. Unlike the bilateral deterrence model of the Cold War—in which two parties maintained stability through mutual assured destruction—the contemporary nuclear order involves nine nuclear-armed states embedded in a complex web of deterrence, assurance, and competition relationships. The Geometry Model maps these relationships along three dimensions: adversarial deterrence (preventing nuclear attack), extended deterrence (reassuring non-nuclear allies), and competitive deterrence (managing rivalry below the nuclear threshold).

The model reveals several structural instabilities. First, actions taken to strengthen deterrence against one adversary may undermine stability with another: US missile defense deployments intended to counter North Korean threats are perceived by China as threatening its retaliatory capability, driving China's nuclear expansion, which in turn is perceived by India as requiring a response. Second, the assurance dimension creates entanglement risks: the credibility of US extended deterrence over allies in Europe and Asia depends on capabilities and postures that adversaries perceive as offensive. Third, the multiplication of nuclear dyads increases the probability that at least one will experience a crisis or miscalculation during any given period.

5. Conclusion

The Second Nuclear Age presents challenges that are qualitatively different from those of the Cold War. The bipolar stability—always more precarious than often assumed—has given way to a multipolar nuclear order in which nine states with diverse capabilities, doctrines, and threat

perceptions must simultaneously manage multiple deterrence relationships in the absence of the arms control frameworks that previously provided transparency, predictability, and constraint. The introduction of destabilizing technologies further complicates this picture by compressing decision timelines, blurring conventional-nuclear thresholds, and introducing AI into the most consequential decisions humans can make.

The risk of nuclear use in 2026 is higher than at any point since the Cuban Missile Crisis. This assessment does not rest on the identification of a single acute crisis but on the structural instability of the multipolar nuclear order itself. Addressing this risk requires new approaches to arms control that move beyond bilateral frameworks, new norms governing AI in nuclear systems, and a sustained diplomatic investment in nuclear risk reduction that recognizes the shared existential interest of all states—nuclear and non-nuclear alike—in preventing the use of these weapons.
